Calvin College

## Introduction

Let's play the children's game: *Twenty Questions*

→ You have 20 questions to guess what I'm thinking about...

What are you trying to do with your questions?

→ *Good* questions \_\_\_\_\_  
to narrow the number of remaining possibilities

→ The game presupposes a hierarchy rooted at  
*Something*, whose subclasses are the roots of  
less general class hierarchies:

→ A good question lets you \_\_\_\_\_  
\_\_\_\_\_ in the hierarchy...

We seem to pick this hierarchy up  
quite early (as children)...

(2/48)

Dept of Computer Science

Calvin College

## Object-Oriented Programming (OOP)

One of the basic aims of the \_\_\_\_\_ is to allow programmers to \_\_\_\_\_ (abstract or concrete) from the real world.

→ OOP supports *hierarchical class relationships*:

→ Each ↑ represents the \_\_\_\_\_ relationship, indicating that the *subclass* \_\_\_\_\_ the attributes of its *superclass*.

→ *Object-oriented analysis & design* (\_\_\_\_\_) uses superclasses and inheritance to \_\_\_\_\_, so that those attributes need not be defined more than once.

Different OO languages have different conventions for representing inheritance, but the concept is the same.

(3/48)

Calvin College

## Example: A Payroll Problem

Suppose we have these kinds of workers on our payroll:

- |                      |                 |
|----------------------|-----------------|
| •Faculty member      | •Administrator  |
| – name               | – name          |
| – id number          | – id number     |
| – dept               | – dept          |
| – salary             | – salary        |
| – research specialty |                 |
| •Staff member        | •Student worker |
| – name               | – name          |
| – id number          | – id number     |
| – dept               | – dept          |
| – hourly rate        | – hourly rate   |
| – hours worked       | – hours worked  |
| – supervisor         |                 |

How can we organize these so as to avoid redundant code?

(4/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

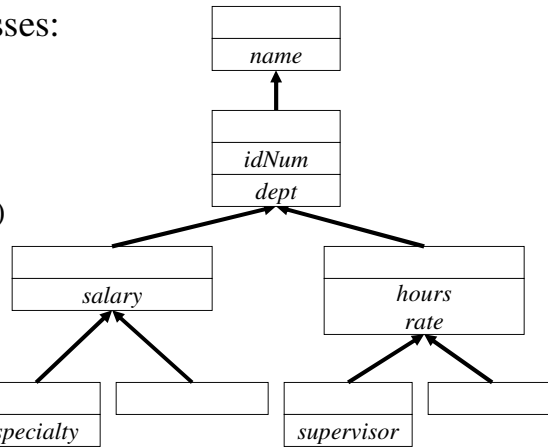

## Design

We can start with the ‘leaf’ classes and consolidate common attributes into superclasses:

Each class should provide:

- *Constructors*
- *Accessor* methods
- *Mutator* methods (maybe)
- *I/O* methods
- *pay* method  
(*Employee* and below)

Note that our \_\_\_\_\_  
process is \_\_\_\_\_,  
not top-down...

(5/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++

Given a design, our \_\_\_\_\_ proceeds \_\_\_\_\_:

```
class Person {  
public:  
    Person();  
    Person(string name);  
    string getName() const;  
    virtual void write(ostream& out) const;  
    virtual void read(istream& in);  
    friend ostream& operator<<(ostream & out, const Person & p);  
    friend istream& operator>>(istream & in, Person & p);  
  
private:  
    string myName;  
};
```

In order for subclasses to override read() and write() with their own definitions, these must be declared as \_\_\_\_\_ methods in C++.

(6/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++ (ii)

```
inline Person::Person() { myName = ""; }  
inline Person::Person(string name) { myName = name; }  
inline string Person::getName() const { return myName; }  
inline void Person::write(ostream& out) const  
{ out << myName << endl; }  
inline void Person::read(istream& in) { getline(in, myName); }  
inline ostream& operator<<(ostream & out, const Person& p)  
{ p.write(out); return out; }  
inline istream& operator>>(istream& in, Person& p)  
{ p.read(in); return in; }
```

Each of these is simple enough to define *inline* in C++  
(i.e., in the header file)...

(7/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++ (iii)

We continue with the *Employee* subclass of *Person*:

```
class Employee : public Person {  
public:  
    Employee();  
    Employee(string name, int id, string dept);  
    int getID() const;  
    string getDept() const;  
    virtual void write(ostream& out) const;  
    virtual void read(istream& in);  
    virtual double pay() const = 0;  
private:  
    int myID;  
    string myDept;  
};
```

*pay()* is a \_\_\_\_\_ function because every *Employee* should  
respond to that message, but \_\_\_\_\_.

(8/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++ (iv)

```
inline Employee::Employee()
: Person()
{ myID = 0; myDept = ""; }

inline Employee::Employee(string name, int id, string dept)
: Person(name)
{ myID = id; myDept = dept; assert(id > 0); }

inline int Employee::getID() const { return myID; }

inline string Employee::getDept() const { return myDept; }

inline void Employee::write(ostream& out) const {
    Person::write(out);
    out << myID << endl << myDept << endl;
}

inline void Employee::read(istream& in) {
    Person::read(in);
    in >> myID >> myDept; assert(myID > 0);
}
```

*Employee* \_\_\_\_\_, and since they call *write()* and *read()*, we need not redefine them...

(9/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++ (v)

We continue with *Employee*'s *SalariedEmployee* subclass:

```
class SalariedEmployee : public Employee {
public:
    SalariedEmployee();
    SalariedEmployee(string name, int id,
                     string dept, double salary);
    double getSalary() const;
    virtual void write(ostream& out) const;
    virtual void read(istream& in);
    virtual double pay() const;

private:
    double    mySalary;
};
```

A *SalariedEmployee* has the information needed to compute its pay,  
so \_\_\_\_\_.

(10/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++ (vi)

```
inline SalariedEmployee::SalariedEmployee()
: Employee()
{ mySalary = 0.0; }

inline SalariedEmployee::SalariedEmployee(string name, int id,
                                           string dept, double salary)
: Employee(name, id, dept)
{ mySalary = salary; assert(mySalary > 0.0); }

inline double SalariedEmployee::getSalary() const
{ return mySalary; }

inline void SalariedEmployee::write(ostream& out) const
{ Employee::write(out);
  out << mySalary << endl; }

inline void SalariedEmployee::read(istream& in)
{ Employee::read(in);
  in >> mySalary; assert(mySalary > 0.0); }

inline double SalariedEmployee::pay() const
{ return mySalary; }
```

(11/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++ (vii)

We continue with the *FacultyMember* subclass:

```
class FacultyMember : public SalariedEmployee {
public:
  FacultyMember();
  FacultyMember(string name, int id, string dept,
                double salary, string specialty);

  string getSpecialty() const;
  virtual void write(ostream& out) const;
  virtual void read(istream& in);

private:
  string    mySpecialty;
};
```

A *FacultyMember* \_\_\_\_\_ the *name*-, *id*-, *department*-, and *salary*-related attributes/methods from its superclass.

(12/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++ (viii)

```
inline FacultyMember::FacultyMember()
: SalariedEmployee()
{ mySpecialty = ""; }

inline FacultyMember::FacultyMember(string name, int id,
                                     string dept, double salary,
                                     string specialty)
: SalariedEmployee(name, id, dept, salary)
{ mySpecialty = specialty; }

inline string FacultyMember::getSpecialty() const
{ return mySpecialty; }

inline void FacultyMember::write(ostream& out) const
{ SalariedEmployee::write(out);
  out << mySpecialty << endl; }

inline void FacultyMember::read(istream& in)
{ SalariedEmployee::read(in);
  in >> mySpecialty; }
```

We then do the same for the other classes in our design.

(13/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: C++ (ix)

The *Administrator* class is especially easy:

```
class Administrator : public SalariedEmployee {
public:
    Administrator();
    Administrator(string name, int id, string dept,
                  double salary);
};

inline Administrator::Administrator() : SalariedEmployee()
{}

inline Administrator::Administrator(string name, int id,
                                     string dept, double salary)
: SalariedEmployee(name, id, dept, salary)
{}

```

Our *Administrator* class is this simple because \_\_\_\_\_  
\_\_\_\_\_ beyond those it inherits from its superclass...

(14/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Use: C++

Given our hierarchy, we can write something like this:

```
// ...
ifstream fin("payroll.data");
Employee* empPtr; char empType;
for (;;) {
    fin >> empType;
    if ( fin.eof() ) break;
    switch (empType) {
        case 'A': empPtr = new Administrator(); break;
        case 'F': empPtr = new FacultyMember(); break;
        case 'S': empPtr = new StaffMember(); break;
        case 'W': empPtr = new StudentWorker(); break;
    }
    fin >> (*empPtr); // equivalent to empPtr->read(fin);
    cout << empPtr->getName() << endl
         << empPtr->pay() << endl;
}
fin.close();
// ...
```

Our variable *empPtr*  
is called a \_\_\_\_\_,  
because it can 'grab'  
different objects...

(15/48)

Dept of Computer Science

Calvin College

## Compile-Time vs Run-Time Binding

In C++, the *virtual* keyword tells the compiler to \_\_\_\_\_ to bind messages to their definition (by default, binding occurs at \_\_\_\_\_ in C++).

If we don't declare prototypes of *write()* as *virtual*:

```
class Employee {
public:
    // ...
    void write(ostream& out) const;
    // ...
};
```

then subsequent calls to *write()*:

```
Employee* empPtr;
// ...
empPtr->write(cout);
```

are statically bound to *Employee::write()* at \_\_\_\_\_ (because the handle is an *Employee\**) instead of being dynamically bound to the receiver's *write()* at \_\_\_\_\_.

(16/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Polymorphism

By declaring  
*read()* and  
*write()* as  
*virtual*:

```
class Person {  
    // ...  
    virtual void write(ostream& out) const;  
    virtual void read(istream& in);  
    // ...  
};
```

subsequent calls to  
these methods:

```
Employee* empPtr;  
// ...  
empPtr->write(cout);
```

are bound to the *receiver's* definitions of those methods at *run-time*.

- The same call to *write()* may thus invoke *FacultyMember::write()*, *Administrator::write()*, *StaffMember::write()* or *StudentWorker::write()* depending on the object to which the handle *empPtr* points.
- This behavior is called \_\_\_\_\_, or \_\_\_\_\_.
- \_\_\_\_\_ (aka *runtime binding*) is the mechanism by which a message is bound according to *the receiver's type*, instead of the handle's type.

(17/48)

Dept of Computer Science

Calvin College

## Implementation: Java

Let's compare our C++ implementation to Java:

```
public class Person {  
    public Person() { myName = ""; }  
    public Person(String name) { myName = name; }  
    public final String getName() { return myName; }  
    public void write(PrintWriter out) { out.println(myName); }  
    public void read(BufferedReader in) { myName = in.readLine(); }  
  
    private String myName;  
}
```

Java has no operator overloading, no const methods and no friends.

In C++, compile-time binding is the default; run-time binding (polymorphism) must be enabled using the *virtual* keyword.

In Java, \_\_\_\_\_;  
compile-time binding must be enabled using the \_\_\_\_\_ keyword.

(18/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Java (ii)

Continuing with the *Employee* subclass of *Person*:

```
abstract class Employee extends Person {
    public Employee() { super(); myID = 0; myDept = ""; }
    public Employee(String name, int id, String dept)
    { super(name); myID = id; myDept = dept; }

    public final int getID() { return myID; }
    public final String getDept() { return myDept; }

    public void write(PrintWriter out)
    { super.write(out); out.println(myID); out.println(myDept); }

    public void read(BufferedReader in)
    { super.read(in); String idString = in.readLine();
      myID = Integer.parseInt(idString); myDept = in.readLine(); }

    abstract public double pay();    // "pure virtual" in Java
    private int    myID;
    private String myDept;
}
```

(19/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Java (iii)

```
class SalariedEmployee extends Employee {
    public SalariedEmployee() { super(); mySalary = 0.0; }

    public SalariedEmployee(String name, int id,
                           String dept, double salary)
    { super(name, id, dept); mySalary = salary; }

    public final double getSalary() { return mySalary; }

    public void write(PrintWriter out)
    { super.write(out); out.println(mySalary); }

    public void read(BufferedReader in)
    { super.read(in); String salaryString = in.readLine();
      mySalary = Double.parseDouble(salaryString); }

    public double pay() { return mySalary; }
    private double mySalary;
}
```

Java lets us do most of the same things, but (usually) more easily...

(20/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Java (iv)

```
class FacultyMember extends SalariedEmployee {  
    public FacultyMember() { super(); mySpecialty = ""; }  
    public FacultyMember(String name, int id, String dept,  
                           double salary, String specialty)  
        { super(name, id, dept, salary); mySpecialty = specialty; }  
  
    public final String getSpecialty() { return mySpecialty; }  
  
    public void write(PrintWriter out)  
        { super.write(out); out.println(mySpecialty); }  
  
    public void read(BufferedReader in)  
        { super.read(in); mySpecialty = in.readLine(); }  
  
    private String mySpecialty;  
}
```

We then implement the other classes the same way...

(21/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Java (v)

As before, *Administrator* indicates how easy this is:

```
class Administrator extends SalariedEmployee {  
    public Administrator() { super(); }  
  
    public Administrator(String name, int id, String dept,  
                           double salary)  
        { super(name, id, dept, salary); }  
  
}
```

Our *Administrator* class is this simple because it has no attributes/methods beyond those it inherits from its superclass...

(22/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Use: Java

To use these classes, we can write something like this:

```
// ...
BufferedReader fin = new BufferedReader(
    new InputStreamReader(
        new FileReader("payroll.data")));
Employee emp = null; String eType = null;
for (;;) {
    eType = fin.readLine();           // name of class
    if ( eType == null ) break;
    Employee emp = (Employee) Class.forName(eType).newInstance();
    emp.read(fin);
    System.out.println( emp.getName() + "\n" + emp.pay() );
}
fin.close();
// ...
```

All non-primitive-type variables are \_\_\_\_\_ in Java.  
Java's *Class* class provides a very convenient way to build an instance  
of a class from a string whose value is the name of the class.

(23/48)

Dept of Computer Science

Calvin College

## Implementation: Ada

Let's compare Ada to our other implementations:

```
package PersonPackage is
    type Person is tagged private;
    type PersonRef is access all Person'Class;
    procedure Init(P: in out Person; AName: Unbounded_String);
    function GetName(P: in Person) return Unbounded_String;
    procedure Read(F: in out File_Type; P: in out Person);
    procedure Write(F: in out File_Type; P: in Person);
    procedure Put(F: in out File_Type; P: in Person'Class);
    procedure Get(F: in out File_Type; P: in out Person'Class);
private
    type Person is tagged record
        itsName : Unbounded_String;
    end record;
end PersonPackage;
```

In Ada, a *subtype* can inherit from a *tagged* type (for polymorphism);  
and a *handle* is declared as a pointer to a *Class-wide* type.

(24/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Ada (ii)

Our package body is as follows:

```
package body PersonPackage is
  procedure Init(P: in out Person; AName: Unbounded_String) is
  begin
    P.ItsName := AName;
  end Init;
  function GetName(P: in Person) return Unbounded_String is
  begin
    return P.ItsName;
  end GetName;

  procedure Write(F: in out File_Type; P: in Person) is begin
    Put(F, P.ItsName); New_Line(F);
  end Write;

  procedure Put(F: in out File_Type; P: in Person'Class) is
  begin
    Write(F, P); -- P is class-wide -> dynamic dispatch
  end Put;
  -- ... Read, Get are similar ...

end PersonPackage;
```

(25/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Ada (iii)

We then build *Employee* as an extension of *Person*:

```
package EmployeePackage is
  type Employee is abstract new Person with private;
  type EmployeeRef is access all Employee'Class;
  procedure Init(E: in out Employee; name: Unbounded_String;
    id: Integer; dept: Unbounded_String);
  function GetID(E: in Employee) return Integer;
  function GetDept(E: in Employee) return Unbounded_String;
  procedure Write(F: in out File_Type; E: in Employee);
  procedure Read(F: in out File_Type; E: in out Employee);
  function GetPay(E: in Employee'Class) return float;
  function Pay(E: in Employee) return float is abstract;

private
  type Employee is abstract new Person with record
    itsID : Integer;
    itsDept : Unbounded_String;
  end record;
end EmployeePackage;
```

(26/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Ada (iv)

```
package body EmployeePackage is
  procedure Init(E: in out Employee; Name: in Unbounded_String;
                Id: in Integer; Dept: in Unbounded_String)
  is begin
    Init(Person(E), Name); E.ItsID := Id; E.ItsDept := Dept;
  end Init;

  function GetId(E: in Employee) return Integer is begin
    return Emp.ItsId;
  end GetId;

  -- ... GetDept() is similar ...

  procedure Write(F: in out File_Type; E: in Employee) is begin
    Write(F, Person(E));
    Put(F, E.ItsId); New_line(F);
    Put(F, E.ItsDept); New_Line(F);
  end Write;

  -- ... read(F, E) is similar; Get(F,E), Put(F,E) are not needed!

  function GetPay(E: in Employee'Class) return float is begin
    return Pay(E);    // E is class-wide -> dynamic dispatch
  end GetPay;
end EmployeePackage;
```

Dept of Computer Science

Calvin College

## Implementation: Ada (v)

We then build *SalariedEmployee* as an extension of *Employee*:

```
package SalariedEmployeePackage is
  type SalariedEmployee is new Employee with private;
  type SalariedEmployeeRef is access all SalariedEmployee'Class;

  procedure Init(sE: in out SalariedEmployee;
                Name: in Unbounded_String; Id: in Integer;
                Dept: in Unbounded_String; Salary: in Float);

  function GetSalary(sE: in SalariedEmployee) return Float;

  procedure Write(F: in out File_Type; sE: in SalariedEmployee);

  procedure Read(F: in out File_Type;
                sE: in out SalariedEmployee);

  function Pay(sE: in SalariedEmployee) return Float;

private
  type SalariedEmployee is new Employee with record
    itsSalary : Float;
  end record;
end SalariedEmployeePackage;
```

(28/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Ada (vi)

```
package body SalariedEmployeePackage is
  procedure Init(sE: in out SalariedEmployee;
    Name: in Unbounded_String; Id: in Integer;
    Dept: in Unbounded_String; Salary: in Float)
  is begin
    Init(Employee(sE), Name, Id, Dept); sE.ItsSalary := Salary;
  end Init;
  function GetSalary(sE: in SalariedEmployee) return Float is
  begin
    return sE.ItsSalary;
  end GetSalary;
  procedure Write(F: in out File_Type; sE: out SalariedEmployee)
  is begin
    Write(F, Employee(sE));
    Put(F, sE.ItsSalary); New_line(F);
  end Write;
  -- ... Read(F, sE) is similar...
  function Pay(sE: in SalariedEmployee) return Float is begin
    return mySalary;
  end Pay;
end SalariedEmployeePackage ;
```

(29/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Ada (vii)

We then build *Faculty* as an extension of *SalariedEmployee*:

```
package FacultyPackage is
  type Faculty is new SalariedEmployee with private;
  type FacultyRef is access all Faculty'Class;

  procedure Init(F: in out Faculty; Name: in Unbounded_String;
    Id: in Integer; Dept: in Unbounded_String;
    Salary: in Float; Specialty: in Unbounded_String);
  function GetSpecialty(F: in Faculty) return Unbounded_String;
  procedure Write(outf: in out File_Type; F: in Faculty);
  procedure Read(inF: in out File_Type; F: in out Faculty);

private
  type Faculty is new SalariedEmployee with record
    itsSpecialty : Unbounded_String;
  end record;
end FacultyPackage;
```

(30/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Ada (viii)

```
package body FacultyPackage is
  procedure Init(F: in out Faculty; Name: in Unbounded_String;
               Id: in Integer; Dept: in Unbounded_String;
               Salary: in Float; Specialty: in Unbounded_String)
  is begin
    Init(SalariedEmployee(F), Name, Id, Dept, Salary);
    F.ItsSpecialty := Specialty;
  end Init;

  function GetSpecialty(F: in Faculty) return Unbounded_String
  is begin
    return F.ItsSpecialty;
  end GetSpecialty;

  procedure Write(outf: in out File_Type; F: in Faculty) is
  begin
    Write(outf, SalariedEmployee(F));
    Put(outf, F.ItsSpecialty); New_Line(F);
  end Write;

  -- ... Read(outf, F) is similar...
end FacultyPackage ;
```

(31/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Ada (ix)

We then build *Administrator* as an extension of *SalariedEmployee*:

```
package AdministratorPackage is
  type Administrator is new SalariedEmployee with private;
  type AdministratorRef is access all Administrator'Class;

  private
    type Administrator is new SalariedEmployee with record
      null;
    end record;
end AdministratorPackage;
```

Class *Administrator* inherits everything it needs from its superclass *SalariedEmployee*, so its package body is empty:

```
package body AdministratorPackage is
  -- empty body; Administrator defines no new attributes
end AdministratorPackage ;
```

## Use: Ada

```

Procedure payroll is
  EmpRef : EmployeeRef; fin: File_Type;
  eType: Character; Discard: Unbounded_String;
begin
  Open(fin, In_File, "payroll.dat");
  loop
    Get(fin, eType); Discard := Get_Line(fin); // 'F', 'A', ...
    exit when End_Of_File(fin);
    if empType = 'F' then EmpRef := new Faculty;
    elsif empType = 'A' then EmpRef := new Administrator;
    elsif empType = 'S' then EmpRef := new StaffMember;
    elsif empType = 'W' then EmpRef := new StudentWorker;
    end if;
    Get(EmpRef.all, fin);
    Put( GetName(EmpRef.all) ); New_Line;
    Put( GetPay(EmpRef.all) ); New_Line;
  end loop;
  close(fin);
// ...
OO capabilities are an add-on in Ada, and they feel like it...

```

## Implementation: Smalltalk

Smalltalk's GUI makes  
it easy to build our  
*Person* class:

We provide an *initialization*  
instance method:

*Person* inherits the *new* (class method) constructor from *Object*:

This allows us to write: `p := Person new name: 'Ann'.`  
to *construct* and *initialize* a *Person*.

(34/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (ii)

The *name accessor* is easy:

And to facilitate output, we define *printString* for a *Person*:

System Browser			
Alice2.0-Undo	Person	mutators	getName
Alt-Classes	StackTester	accessors	
Alice2.0-Interface	instance ? class	utilities	
<b>getName</b> ↑ myName			

System Browser			
Alice2.0-Worlds	Employee	-- all --	printString
Alice2.0-Undo	Person	mutators	
Alt-Classes	StackTester	accessors	
Alice2.0-Interface	instance ? class	utilities	
<b>printString</b> ↑ myName, '			

Note that Smalltalk allows strings to contain *embedded newlines*, which we use to separate *myName* from what follows it...

(35/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (iii)

We might define a *read:* method as follows:

System Browser			
My Stuff	Employee	-- all --	printString
Alice2.0-Worlds	Faculty	initializer	read:
Alice2.0-Undo	Person	accessor	write:
Alt-Classes	instance ? class	utilities	
<b>read: aStream</b> myName ← aStream nextLine. myName notNil ifTrue: [↑ self]. ↑ nil			

plus a *write:* method that uses *printString* to display itself:

System Browser			
Alice2.0-Undo	Person	initializer	printString
Alt-Classes	SalariedEmployee	accessor	read:
Alice2.0-Interface	instance ? class	utilities	write:
<b>write: isStream</b> isStream nextPutAll: self printString			

This lets us write:

```
p := Person new name: 'Ann'.
f := FileStream newFileNamed: 'data.txt'.
p write: f.
```

to create a stream to a file and write a *Person* to it.

(36/48)

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (iv)

We then build our  
*Employee* class as a  
subclass of *Person*:

plus a method to  
*initialize* an  
*Employee*:

System Browser			
Alice2.0-Undo	Employee	-- all --	
Alt-Classes	Person	initializers	
Alice2.0-Interface	StackTester		
	instance ? class		
Person subclass: #Employee instanceVariableNames: 'myId myDept' classVariableNames: '' poolDictionaries: '' category: 'Alt-Classes'			

System Browser			
Alice2.0-Undo	Employee	-- all --	name:id:dept:
Alt-Classes	Faculty	initializers	
Alice2.0-Interface	instance ? class	accessors	
		utilities	
name: aName id: anID dept: aDept super name: aName. myId ← anID.			

It is good practice to \_\_\_\_\_ (e.g., `super name: aName`)  
:  
 – It \_\_\_\_\_ we invested in writing those methods (avoid redundant code).  
 – If we alter the superclass method, the subclass \_\_\_\_\_.

(37/48)

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (v)

We then define  
*accessors* for the  
instance variables:

*printString* to  
facilitate output  
(using the  
superclass version):

and *pay* as an abstract /  
“pure virtual” method:

System Browser			
Alice2.0-Undo	Employee	-- all --	getDept
Alt-Classes	instance ? class	initializers	getId
Alice2.0-Interface		accessors	
getDept ↑ myDept			

System Browser			
Alice2.0-Undo	Employee	-- all --	getDept
Alt-Classes	instance ? class	initializers	getId
Alice2.0-Interface		accessors	
getId ↑ myId			

System Browser			
Alice2.0-Undo	Employee	-- all --	printString
Alt-Classes	instance ? class	initializers	
Alice2.0-Interface		accessors	
printString ↑ super printString , myId printString , , myDept ,			

System Browser			
Alice2.0-Undo	Employee	-- all --	getDept
Alt-Classes	instance ? class	initializers	getId
Alice2.0-Interface		accessors	pay
pay self subclassResponsibility			

(38/48)

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (vi)

We can then  
override *read*:  
as follows:

System Browser			
My Stuff	Employee	-- all --	printString
Alice2.0-Worlds	Faculty	initializers	read:
Alice2.0-Undo	Person	accessors	
Alt-Classes	instance ? class	utilities	

```

read: aStream
  super read: aStream.
  myId ← aStream nextLine asNumber.
  myDept ← aStream nextLine.
  ↑ myDept
  
```

Because (i) the  
*write*: we inherit  
from *Person* \_\_\_\_\_  
\_\_\_\_\_ to  
display itself,

System Browser			
Alice2.0-Undo	Person	initializer	printString
Alt-Classes	SalariedEmployee	accessor	read:
Alice2.0-Interface	instance ? class	utilities	write:

```

write: isStream
  isStream nextPutAll: self printString
  
```

(ii) we have defined *printString* in class *Employee*, and  
(iii) \_\_\_\_\_ Smalltalk methods are *polymorphic*,  
the *write*: we inherit from *Person* will correctly output an *Employee*...

(39/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (vii)

We then build our  
*SalariedEmployee* class  
as a subclass of  
*Employee*:

System Browser			
Alice2.0-Worlds	Employee	-- all --	
Alice2.0-Undo	Person	initializers	
Alt-Classes	SalariedEmployee	accessors	
Alice2.0-Interface	instance ? class	utilities	

```

Employee subclass: #SalariedEmployee
  instanceVariableNames: 'mySalary'
  classVariableNames: ''
  poolDictionaries: ''
  category: 'Alt-Classes'
  
```

plus a method to  
*initialize* an  
*SalariedEmployee*:

System Browser			
Alice2.0-Worlds	Employee	-- all --	name: id: dept: salary:
Alice2.0-Undo	Person	initializers	
Alt-Classes	SalariedEmployee	accessors	
Alice2.0-Interface	instance ? class	utilities	

```

name: aName id: anId dept: aDept salary: aSalary
  super name: aName id: anId dept: aDept.
  mySalary ← aSalary
  
```

As before, we \_\_\_\_\_  
and thus recoup the work we invested in writing them.

(40/48)

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (viii)

We then define an *accessor* for our instance variable:

*printString* to facilitate output:

and the polymorphic *pay* method:

System Browser			
Alice2.0-Undo	SalariedEmployee	-- all --	getSalary
Alt-Classes		initializers	
Alice2.0-Interface	instance ? class	accessors	
<b>getSalary</b>			
↑ mySalary			

System Browser			
Alice2.0-Worlds	Employee	-- all --	printString
Alice2.0-Undo	Person	initializers	
Alt-Classes	SalariedEmployee	accessors	
Alice2.0-Interface	instance ? class	utilities	
<b>printString</b>			
↑ super printString , mySalary printString , '			

System Browser			
Alice2.0-Undo	SalariedEmployee	-- all --	pay
Alt-Classes		initializers	
Alice2.0-Interface	instance ? class	accessors	
<b>pay</b>			
↑ mySalary			

(41/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (ix)

We can then override *read*: as follows:

System Browser			
My Stuff	Faculty	-- all --	printString
Alice2.0-Worlds	Person	initializers	read:
Alice2.0-Undo	SalariedEmployee	accessors	
Alt-Classes	instance ? class	utilities	
<b>read: aStream</b>			
super read: aStream.			
mySalary ← aStream nextLine asNumber.			
↑ mySalary			

As before, our definition of (polymorphic) *printString* means that the *write*: we inherit from *Person* will correctly output a *SalariedEmployee* without any further work on our part.

We could have performed input similarly, if we had defined *read*: in *Person* to use `self fromString` and then defined *fromString* in *Person* and each of its subclasses.

(42/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (x)

We then build our *Faculty* class as a subclass of *SalariedEmployee*:

plus methods to *initialize*:

and *access* its instance variable:

System Browser			
Alice2.0-Worlds	Employee	-- all --	
Alice2.0-Undo	Faculty	as yet unclassified	
Alt-Classes	Person		
Alice2.0-Interface	instance ? class		
SalariedEmployee subclass: #Faculty			
instanceVariableNames: 'mySpecialty'			
classVariableNames: ''			
poolDictionaries: ''			
category: 'Alt-Classes'			

System Browser			
Alice2.0-Worlds	Employee	-- all --	name: id: dept: salary:
Alice2.0-Undo	Faculty	accessors	
Alt-Classes	Person	initializers	
Alice2.0-Interface	instance ? class		
name: aName id: anId dept: aDept salary: aSalary specialty: aSpecialty			
super name: aName id: anId dept: aDept salary: aSalary.			
mySpecialty ← aSpecialty			

System Browser			
Alice2.0-Undo	Faculty	-- all --	getSpecialty
Alt-Classes	Person	accessors	
Alice2.0-Interface	instance ? class	initializers	
getSpecialty			
↑ mySpecialty			

(43/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (xi)

We then define *printString* to facilitate output:

and override *read:* to provide input:

System Browser			
Alice2.0-Worlds	Employee	-- all --	printString
Alice2.0-Undo	Faculty	accessors	
Alt-Classes	Person	initializers	
Alice2.0-Interface	instance ? class	utilities	
printString			
↑ super printString , mySpecialty , '			

System Browser			
My Stuff	Faculty	-- all --	printString
Alice2.0-Worlds	Person	initializers	read:
Alice2.0-Undo	SalariedEmployee	accessors	
Alt-Classes	instance ? class	utilities	
read: aStream			
super read: aStream.			
mySpecialty ← aStream nextLine.			
↑ mySpecialty			

We then build the other classes in our design in a similar fashion, using inheritance and polymorphism to avoid redundant coding...

(44/48)

© Joel C. Adams. All Rights Reserved.

Dept of Computer Science

Calvin College

## Implementation: Smalltalk (xii)

*Administrator* indicates how easy this is:

The class has no  
attributes beyond  
what it inherits from  
its superclass:

System Browser			
My Stuff	Administrator	-- all --	
Alice2.0-Worlds	Employee	no messages	
Alice2.0-Undo	Faculty		
Alt-Classes	instance ? class		
SalariedEmployee subclass: #Administrator			
instanceVariableNames: ''			
classVariableNames: ''			
poolDictionaries: ''			
category: 'Alt-Classes'			

And since Smalltalk separates *construction* from *initialization*:

- Construction is via *new* inherited from \_\_\_\_\_;
- Initialization is via *name:id:dept:salary* inherited from \_\_\_\_\_;

we're done with *Administrator*!

(45/48)

Dept of Computer Science

Calvin College

## Use: Smalltalk

Given the class  
hierarchy our  
design calls for,  
we can write  
something like  
this as the *run*  
method of a  
class that solves  
our payroll  
problem:

```

| inFile emp empType |
inFile := FileStream oldFileName: 'test.in'.
[(empType := inFile nextLine) notNil]
whileTrue: [
    empType = 'f'
    ifTrue: [ emp := Faculty new ]
    ifFalse: [
        empType = 'a'
        ifTrue: [ emp := Administrator new ]
        ifFalse: [
            empType = 's'
            ifTrue: [ emp := StaffMember new ]
            ifFalse: [
                empType = 'w'
                ifTrue: [ emp := StudentWorker new ]
                ifFalse: [ "... display an error-alert..." ] ] ] ]
    emp read: inFile.
    Transcript show: emp name; cr;
    show: (emp pay printString); cr
].
inFile close.

```

(46/48)

Dept of Computer Science

Calvin College

## Summary

*Object-oriented programming* (OOP) is a way to build a system made up of a hierarchy of classes that reflects \_\_\_\_\_.

- A *subclass* inherits the \_\_\_\_\_ (data + operations) of its *superclass*.
- \_\_\_\_\_ ensures that when a message is sent to an object, the message is delivered to that object *first*:
  - If its class defines that message, that definition is invoked;
  - Otherwise, the message is sent “upward” in the hierarchy to the parent class, where the process is repeated.
  - If the message reaches the root class without finding a definition, a run-time error occurs.

This is called \_\_\_\_\_, because the same message: *handle msg* may produce very different behaviors, depending on the receiver.

Dept of Computer Science

Calvin College

## Summary (ii)

“OO” languages differ in how easy/simple they make OOP:

language/ binding	Ada	C++	Java	Smalltalk
compile time (static)				
run time (dynamic)				

“OO” languages thus lie on an OO continuum:

less OO ← → more OO
